1. Add Product Class in the Model Folder. And write some properties inside this product class

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Web;

namespace RestModule2.Models
{
    public class Product
    {
        public int Id { get; set; }
        public string ProductName { get; set; }
        public double Price { get; set; }
    }
}
```

2. Then in the ProductsController just replace the First Get Method with the following lines of code …

```csharp
// GET: api/Products
        public IQueryable<Product> GetProducts(string sortPrice)
        {
            IQueryable<Product> products;

            switch (sortPrice)
            {
                case "desc":
                    products = db.Products.OrderByDescending(p => p.Price);
                    break;
                case "asc":
                    products = db.Products.OrderBy(p => p.Price);
                    break;
                default:
                    products = db.Products;
                    break;
            }
            return products;
        }
```
